Quantification of Lathosterol as a Biomarker in Human Plasma

Using UPLC-MS/MS System

Overview

A rapid, sensitive and specific analytical method has been developed and validated to quantify lathosterol as a biomarker in human KEDTA plasma for clinical studies. In this method, lathosterol was extracted from 0.05 mL of human KEDTA plasma using simple extraction procedures. Separation was performed on a reverse phase column (Thermo Hypersil C18 Gold). Detection was achieved using an ABSCIEX QTRAP 5500 system in the positive ion mode with multiple reaction monitoring (MRM). The lower limit of quantitation was 0.1 µg/mL.

Introduction

Lathosterol, the direct precursor of cholesterol, is an indicator of whole-body cholesterol synthesis in humans. The ratio of lathosterol to cholesterol in serum or plasma is often used for predicting the effect of cholesterol-lowering drugs in clinical studies. GC or GC-MS methods were commonly used for lathosterol and other sterols analysis, however, the extraction procedure was very tedious and GC separation was very time-consuming. Some LC/MS/MS methods were reported but separation of lathosterol from cholesterol was an issue since both lathosterol and cholesterol have the same molecular weight and very similar structures. Cholesterol could camouflage lathosterol peak since cholesterol is in a much higher level in plasma (cholesterol: lathosterol>1000). In this study, we used a UPLC system to achieve a good separation of lathosterol, cholesterol and other analogues, coupled with a tandem mass spectrometry in positive APCl mode for the quantification of lathosterol in human plasma.

Structure

Lathosterol

25-Hydroxycholesterol-d_4

Sample Preparation:

Due to endogenous presence of lathosterol, a surrogate matrix was used for the preparation of calibration standards and LLOQ and LQC samples, however, MQC and HQC samples were prepared in authentic human plasma. Lathosterol and its internal standard were extracted from an aliquot of 50 µL plasma using liquid-liquid extraction method. The supernatant was dried, reconstituted and transferred to a 96-Well plate for LC-MS/MS analysis.

Liquid Chromatography:

Pump: Shimadzu UFLC LC-30AD
AutoSampler: Shimadzu UFLC SIL-30AC
System Controller: Shimadzu CMB-30A
Analytical Column: Thermo Hypersil GOLD column, 2 x 100 mm, 1.9 µm
Isotric Flow: The analytes were eluted using an isocratic flow of mobile phase A (0.1% formic acid/mobile phase B (0.1% formic acid in methanol) (17:83, v/v)
Injection Volume: 5 µL

Mass Spectrometry:

MS System: ABSciex QTRAP 5500
Condition: APCl (+) MS/MS,
MRM Transition: Lathosterol: 369.4 → 95.1, 25-Hydroxycholesterol-d_4: 375.6 → 95.1

Conclusions

A rapid, simple and specific LC-MS/MS method has been developed and validated for quantifying Lathosterol with a lower limit of quantitation of 0.1 µg/mL, using 0.05 mL plasma sample.

• Excellent linearity was obtained with a correlation coefficient ≥ 0.9913 for lathosterol. The high dynamic calibration range was achieved due to reduced background noise (Figures 1 to 4).
• For Lathosterol, including LLOQ, the inter-day CV ranged from 5.1% to 13.4% and the biases of the means ranged from -10.4% to 0.4%. In addition, Lathosterol was found to be stable in human plasma after 24 hours at ambient temperature, through three freeze/thaw cycles from -70°C, and after 32 days long-term stored in freezer at -70°C (Table 1). These results also indicate that the liquid-liquid extraction method is suitable for lathosterol, as well as its related sterols analysis.
• Lathosterol has the same molecular weight as that of cholesterol and the high ratio of cholesterol:lathosterol (>1000:1) is in blood stream, our LC-MS/MS condition was used to achieve a good separation of lathosterol, cholesterol and other analogues.
