### Observational Study of Postmenopausal Women on Therapies for Bone Loss

This was a multi-center prospective observational study of postmenopausal women on therapies for bone loss. Conducted at 137 US sites, including general practice, family medicine, and obstetrics/gynecology practices, the study was designed to minimize impact on clinical management of subjects. Patients were enrolled over a two-year period and were followed for up to three years. The primary objective was to determine the pattern of care and health and economic outcomes associated with the management of bone loss in postmenopausal women. These outcomes included usage of, and compliance with, therapeutic regimens for osteoporosis/osteopenia, patient reported rates of AEs, and treatment satisfaction as well impacts on quality of life and workplace productivity. Clinical, PRO, and other data were collected from 6,000 patients. Data collection methods included a baseline questionnaire provided at the baseline clinic visit and follow-up questionnaires that were sent directly to patients at six-month intervals. A subset of patient data was validated against relevant claims data.
